

COVID 19 US Total Case and Death Estimates & Forecasts

Viole, Fred

April 13, 2020

1 Install latest NNS (0.5.1)

```
# Install NNS >= 0.5.1, uncomment next line if NNS >= 5.1 not installed already
# library(devtools); install_github('OVVO-Financial/NNS', ref = "NNS-Beta-Version")
library(NNS)
library(data.table)
library(xtable)
```

2 Read and convert data

NY Times covid 19 data repository: <https://github.com/nytimes/covid-19-data>

```
data <- read.csv("https://raw.githubusercontent.com/nytimes/covid-19-data/master/us-states.csv",
                header = TRUE, sep = ",")
data <- data.table(data)
# US Totals
totals <- data[, lapply(.SD, sum), .SDcols = c("cases","deaths"), by = date]
# NY NJ Specific
ny_nj_totals <- data[state%in%c("New York", "New Jersey"), lapply(.SD, sum),
                    .SDcols = c("cases","deaths"), by = date]
```

3 Create growth rate for total cases

In this step, we are doing a univariate time-series estimation of the observed growth rate in **total cases**. We use **NNS.ARMA** on cross-validated parameters via the **NNS.ARMA.optim** function.

```
new_cases_rate <- log(totals$cases/shift(totals$cases,1))
new_cases_rate <- new_cases_rate[-1]
l <- length(new_cases_rate)
a <- NNS.seas(new_cases_rate, modulo = 7)
b <- NNS.ARMA.optim(new_cases_rate, training.set = 1-14, seasonal.factor = a$periods,
                    print.trace = FALSE)
new_cases_rate_est <- NNS.ARMA(new_cases_rate, h = 14, seasonal.factor = b$periods,
                               weights = b$weights) + b$bias.shift

# NY NJ Specific
ny_nj_new_cases_rate <- log(ny_nj_totals$cases/shift(ny_nj_totals$cases,1))
ny_nj_new_cases_rate <- ny_nj_new_cases_rate[-1]
l <- length(ny_nj_new_cases_rate)
a <- NNS.seas(ny_nj_new_cases_rate, modulo = 7)
b <- NNS.ARMA.optim(ny_nj_new_cases_rate, training.set = 1-14, seasonal.factor = a$periods,
                    print.trace = FALSE)
```

```
# Test 60 days out to find 0 intercept
ny_nj_new_cases_rate_est <- NNS.ARMA(ny_nj_new_cases_rate, h = 14, seasonal.factor = b$periods,
                                     weights = b$weights) + b$bias.shift
```

3.1 Smooth growth rate point estimates and generate CI

With this new **extended growth rate** time series, we smooth the point estimates provided and generate a 0.95 confidence interval using $\pm 2\sigma$ of the observed growth rates. The image below is the regression of the **extended growth rate**. 0 is the critical point to achieve.

```
new_cases_rate_est_raw <- c(new_cases_rate, new_cases_rate_est)
new_cases_rate_est <- c(new_cases_rate, new_cases_rate_est)
new_cases_rate_est <- NNS.reg(seq_len(length(new_cases_rate_est)), new_cases_rate_est,
                             point.est = tail(1:length(new_cases_rate_est),14))$Point.est
new_cases_rate_est <- new_cases_rate_est + 1
# NY NJ Specific
ny_nj_new_cases_rate_est_raw <- c(ny_nj_new_cases_rate, ny_nj_new_cases_rate_est)
ny_nj_new_cases_rate_est <- c(ny_nj_new_cases_rate, ny_nj_new_cases_rate_est)
ny_nj_new_cases_rate_est <- NNS.reg(seq_len(length(ny_nj_new_cases_rate_est)),
                                   ny_nj_new_cases_rate_est,
                                   point.est = tail(1:length(ny_nj_new_cases_rate_est), 14),
                                   plot = FALSE)$Point.est

# US Lower CI Case rate
new_cases_rate_est_lower <- pmax(0, new_cases_rate_est_raw - 2 * sd(new_cases_rate_est_raw))
new_cases_rate_est_lower <- c(new_cases_rate, new_cases_rate_est_lower)
new_cases_rate_est_lower <- NNS.reg(seq_len(length(new_cases_rate_est_lower)),
                                   new_cases_rate_est_lower,
                                   point.est = tail(1:length(new_cases_rate_est_lower), 14),
                                   plot = FALSE)$Point.est
new_cases_rate_est_lower <- new_cases_rate_est_lower + 1
# US Upper CI Case rate
new_cases_rate_est_upper <- new_cases_rate_est_raw + 2 * sd(new_cases_rate_est_raw)
new_cases_rate_est_upper <- c(new_cases_rate, new_cases_rate_est_upper)
new_cases_rate_est_upper <- NNS.reg(seq_len(length(new_cases_rate_est_upper)),
                                   new_cases_rate_est_upper,
                                   point.est = tail(1:length(new_cases_rate_est_upper), 14),
                                   plot = FALSE)$Point.est
new_cases_rate_est_upper <- new_cases_rate_est_upper + 1
```

NNS Order = 3

4 Apply growth rates to estimate total cases

Using the growth rates from the above step, we can now apply them to the last known value of **total cases** and extrapolate. We do this for the **lower growth rate** as well as the **upper growth rate**.

```
cases_est <- numeric()
for(i in 1:length(new_cases_rate_est)){
  if(i > 1){
    cases_est[i] <- cases_est[i-1]*new_cases_rate_est[i]
  } else {
    cases_est[i] <- tail(totals$cases,1)*new_cases_rate_est[i]
  }
}

lower_cases_est <- numeric()
for(i in 1:length(new_cases_rate_est_lower)){
  if(i > 1){
    lower_cases_est[i] <- lower_cases_est[i-1]*new_cases_rate_est_lower[i]
  } else {
    lower_cases_est[i] <- tail(totals$cases,1)*new_cases_rate_est_lower[i]
  }
}
```

```

upper_cases_est <- numeric()
for(i in 1:length(new_cases_rate_est_upper)){
  if(i > 1){
    upper_cases_est[i] <- cases_est[i-1]*new_cases_rate_est_upper[i]
  } else {
    upper_cases_est[i] <- tail(totals$cases,1)*new_cases_rate_est_upper[i]
  }
}

```

5 Assign death rate and CI

We will use the last observed **death rate**, and apply $\pm 2\sigma$ from the observed death rates to determine a **lower death rate** and an **upper death rate**.

```

death_rate <- totals$deaths/totals$cases
death_rate <- death_rate[-1]
death_rate_est <- tail(death_rate,1)
lower_death_rate_est <- max(0, death_rate_est - 2*sd(death_rate))
upper_death_rate_est <- death_rate_est + 2*sd(death_rate)

```

6 Estimate total deaths from estimated total cases

Using the death rates from the above step, we can now apply them to the estimated total cases in section 4, creating a lower and upper interval for **estimated total deaths**.

```

new_deaths <- c(totals$deaths,death_rate_est*cases_est)
forecast_points <- tail(1:length(new_deaths), 14)
deaths_est <- NNS.reg(seq_len(length(new_deaths)), new_deaths,
  point.est = forecast_points)$Point.est
new_deaths_lower <- c(totals$deaths,lower_death_rate_est*cases_est)
lower_deaths_est <- NNS.reg(seq_len(length(new_deaths_lower)), new_deaths_lower,
  point.est = forecast_points)$Point.est
lower_deaths_est <- pmax(lower_deaths_est, tail(totals$deaths,1))
new_deaths_upper <- c(totals$deaths,upper_death_rate_est*cases_est)
upper_deaths_est <- NNS.reg(seq_len(length(new_deaths_upper)), new_deaths_upper,
  point.est = forecast_points)$Point.est
date <- seq(as.Date(tail(totals$date,1)), by = "day", length.out = 15)[-1]
estimates <- cbind.data.frame(as.character(date),
  cases_est, lower_cases_est, upper_cases_est,
  deaths_est, lower_deaths_est, upper_deaths_est)
colnames(estimates)[1] <- "date"

```

7 Results

7.1 Last known values:

	date	cases	deaths
1	2020-04-07	397754	12956

7.3 Yesterday's Forecasted and Actual Values:

To compare yesterday's forecasted versus the actual reported values (*plus any revisions to existing data*), we can repeat all of the previous steps on the modified dataset by removing the last entry and creating the object **yesterday**.

```
yesterday <- totals[-.N,]  
print(xtable(tail(yesterday)))
```

	date	cases	deaths
1	2020-04-06	366238	10959
2	2020-04-07	397754	12956
3	2020-04-08	429319	14803
4	2020-04-09	463684	16674
5	2020-04-10	496912	18712
6	2020-04-11	528405	20575

```
yesterday_new_cases_rate <- log(yesterday$cases/shift(yesterday$cases,1))  
yesterday_new_cases_rate <- yesterday_new_cases_rate[-1]  
l <- length(yesterday_new_cases_rate)  
a <- NNS.seas(yesterday_new_cases_rate, modulo = 7)  
b <- NNS.ARMA.optim(yesterday_new_cases_rate, training.set = 1-14, seasonal.factor = a$periods,
```

```

        print.trace = FALSE)
yesterday_new_cases_rate_est <- NNS.ARMA(yesterday_new_cases_rate, h = 14,
                                          seasonal.factor = b$periods,
                                          weights = b$weights) + b$bias.shift
yesterday_new_cases_rate_est <- c(new_cases_rate, yesterday_new_cases_rate_est)
yesterday_new_cases_rate_est <- NNS.reg(seq_len(length(yesterday_new_cases_rate_est)),
                                         yesterday_new_cases_rate_est,
                                         point.est = tail(1:length(yesterday_new_cases_rate_est),14))$Point.est
yesterday_new_cases_rate_est <- yesterday_new_cases_rate_est + 1
yesterday_cases_est <- numeric()
for(i in 1:length(yesterday_new_cases_rate_est)){
  if(i >1){
    yesterday_cases_est[i] <- yesterday_cases_est[i-1]*yesterday_new_cases_rate_est[i]
  } else {
    yesterday_cases_est[i] <- tail(yesterday$cases,1)*yesterday_new_cases_rate_est[i]
  }
}
yesterday_death_rate <- yesterday$deaths/yesterday$cases
yesterday_death_rate <- yesterday_death_rate[-1]
yesterday_death_rate_est <- tail(yesterday_death_rate,1)
yesterday_new_deaths <- c(yesterday$deaths, yesterday_death_rate_est*yesterday_cases_est)
yesterday_forecast_points <- tail(1:length(yesterday_new_deaths), 14)
yesterday_deaths_est <- NNS.reg(seq_len(length(yesterday_new_deaths)), yesterday_new_deaths,
                               point.est = yesterday_forecast_points)$Point.est
yesterday_date <- seq(as.Date(tail(yesterday$date,1)), by = "day", length.out = 15)[-1]
yesterday_estimates <- cbind.data.frame(as.character(yesterday_date),
                                       yesterday_cases_est,
                                       yesterday_deaths_est)
colnames(yesterday_estimates)[1] <- "date"

```

7.3.1 Yesterday's Forecast:

```
head(yesterday_estimates, 1)
```

```

      date yesterday_cases_est yesterday_deaths_est
1 2020-04-12          570943          21643.96

```

7.3.2 Yesterday's Actual:

```
tail(totals, 1)
```

```

      date  cases deaths
1: 2020-04-12 555371  22056

```

7.3.3 Yesterday's Forecast Percentage Error:

Yesterday NNS Total Cases Percentage Error:	2.8039%
Yesterday NNS Total Deaths Percentage Error:	-1.8682%

7.3.4 Baseline nls Estimate:

We will use the `nls` function in R to estimate a nonlinear model and compare to **NNS** on yesterday's values. We will use the following nonlinear parametric form:

$$y = \alpha e^{\beta x} + \theta$$

```
theta.0 <- 0 #min(yesterday$cases) * 0.5
# Estimate the rest parameters using a linear model
model.0 <- lm(log(yesterday$cases - theta.0) ~ seq_len(length(yesterday$cases)))
alpha.0 <- exp(coef(model.0)[1])
beta.0 <- coef(model.0)[2]
# Starting parameters
start <- list(alpha = alpha.0, beta = beta.0, theta = theta.0)
model <- nls(yesterday$cases ~ alpha * exp(beta * seq_len(length(yesterday$cases))) + theta,
             data = yesterday, start = start)
coef(model)
```

```
      alpha      beta      theta
89.3565604  0.1072553 -7773.8797824
```

Now forecast the nls model for the next period's **total cases** and apply the same **death rate** estimate used in the **NNS** model.

```
nls_cases_forecast <- coef(model)[1]*exp(coef(model)[2]*(length(yesterday$cases)+1)) + coef(model)[3]
as.numeric(nls_cases_forecast)
```

```
[1] 648820.1
```

```
nls_deaths_forecast <- nls_cases_forecast * yesterday_death_rate_est
as.numeric(nls_deaths_forecast)
```

```
[1] 25263.72
```

Yesterday nls Total Cases Percentage Error:	16.8264%
Yesterday nls Total Deaths Percentage Error:	14.5435%

8 Best Guess When NY/NJ Total Cases Peak

Looking at the NY/NJ `new case rate estimate`, we see it does equal 0. This curve flattening occurs on the following date:

```
as.Date(tail(ny_nj_totals$date,1)) + which(ny_nj_new_cases_rate_est==0)[1]
```

```
[1] "2020-04-20"
```

9 Best Guess When US Total Cases Peak

Looking at the `new case rate est`, there's nothing on the immediate horizon signalling no growth (a rate equal to 1).

```
new_cases_rate_est
```

```
[1] 1.072524 1.063837 1.059927 1.061072 1.062217 1.063362 1.064508 1.065653  
[9] 1.063411 1.059998 1.056584 1.053171 1.049757 1.046344
```

We solve for the number of days by dividing the last `new case rate est - 1` by its last gradient.¹

```
as.Date(tail(totals$date, 1)) + length(new_cases_rate_est) +  
  round(abs((tail(new_cases_rate_est, 1) - 1) / tail(diff(new_cases_rate_est - 1), 1)))
```

```
[1] "2020-05-10"
```

¹The NY/NJ case rate was never applied to estimate a total case estimate, only to estimate the growth rate properties, hence no need to subtract 1.
